TITLE: The chromatographic determination of impurities

PERIODICAL: Neftekhimiya, v.3, no.1, 1963, 135-143

TEXT: The possibility of determining impurities in gas mixtures by ionization detectors and new gas-chromatographic methods was investigated. The dependence of the required number of theoretical plates on the ratio (B) of concentrations of adjacent components was analyzed and the following relationships derived:

$$\frac{N_B}{N_1} = \frac{n^2}{4} \quad ; \quad \text{and for } B \gg 1 \quad \frac{N_B}{N_1} = \frac{\ln B}{2}$$

where N - number of theoretical plates and $n = \sqrt{2 \ln B}$ for $B \gg 1$. Thus for $B = 1000$, the number of theoretical plates in comparison with $B = 1$ should be increased 2.84 times. In general, it is desirable for the main component to be adsorbed more strongly (even irreversibly) than the impurity. This would prevent the latter from being obscured by the tailing of the main component.

Card 1/2

The most promising methods are those developed recently by A.A.Zhukhovitskiy et al and are: 1) thermodynamic method (Dokl. AN SSSR, v.92, 1953, 987), where the mixture is fed continuously into the column subjected to periodic temperature gradient moving in the same direction as the velocity of the furnace; 2) gradient chromatography (Dokl. AN SSSR, v.144, 1962, 829), its advantage being that the diffusional dilution does not lower the concentration of impurities; 3) vacancy chromatography (Dokl. AN SSSR, v.143, 1962, 646), the introduction of the main component into the mixture passed through the column removing its peak (vacancy) in the chromatogram and thus facilitating the determination of the impurity. The methods reveal new possibilities in the analysis of crude oils, natural gas, upper layers of atmosphere and impurities in industrial gaseous mixture. There are 5 figures and 2 tables.

TITLE: On the practicability of the Müller relation for the reflection of β-particles from synthetic mixtures.

PERIODICAL: Zavodskaya laboratoriya, no. 4, 1963, 449 - 453

TEXT: The detailed investigations carried out by Müller (Anal. Chem., 29, 6, 969, 1957) on reflections from a great number of chemical compounds revealed that this reflection is determined by some mean charge Z. The authors conducted investigations to further elucidate the factors determining the reflection from multicomponent systems. It is shown that the intensity of β-radiation reflection is determined by the mean charge of the chemical compound or mechanical mixture; therefore, an analysis of multicomponent systems as to the content of some or even one of the constituents is impossible under general conditions. Moreover, it was found that the intensity of the reflected radiation depends also on the fractionating composition of the powder. The authors describe their tests in detail, whic..

Card 1/2

were carried out with the powders of pure metals, chemical compounds and synthetic binary and ternary mechanical mixtures. They point out that only for systems of micro-nonhomogeneity it is possible to determine the composition of multicomponent systems using the method described. There are 5 figures and 4 tables.

TITLE: Vacantochromatography

PERIODICAL: Zavodskaya laboratoriya, v, 29, no. 1, 1963, 8 - 13

TEXT: A variant of chromatography is suggested in which the mixture to be separated flows continuously through the column and the carrier gas is added in portions. The rules governing the motion of bands in conventional chromatography apply also to the resulting "vacancies" (places containing no substance to be absorbed). Examples of vacantochromatograms are given for hydrocarbon mixtures where the "vacancies" were produced by addition of 0.6 cm^3 air. The asymmetry of peaks is less when using the suggested method than in the usual adsorption chromatography. The area of the "vacancy" peak is proportional to the volume of the carrier gas added. The sensitivity can be increased by moving a temperature field against the flow. Another variant is the addition of carrier gas with a verifying agent, e.g. butane. The impurity concentration can be calcu-

Vacantochromatography

S/032/63/029/001/001/022
B101/B186

lated from the ratio between the peaks of the gaseous impurities in He and the peak of the butane vacancy. Vacantochromatography is particularly recommended for the analysis of low-boiling impurities. The direct use of a flame ionization detector is possible when analyzing noncombustible substances. There are 7 figures and 2 tables.

TITLE: Stepwise chromatography

PERIODICAL: Zavodskaya laboratoriya, v. 29, no. 1, 1963, 14 - 18

TEXT: A simplified form of chromatography is suggested for industrial analyses. Horizontal steps are obtained instead of peaks by introducing in the column large amounts of the mixture to be separated. Complete separation of the substances is not necessary as the height of the steps is such that the components and their concentrations can be determined with the same accuracy as on the basis of the peaks in complete separation. The conditions for the formation of steps are derived from the equation for the separation coefficient and from the dependence of the concentration on diffusion, the Henry coefficient, and the Kramp function. A column twice as long as that used in detection chromatography is needed, and the Henry coefficient must be much greater than unity. Complete separation of the steps is not necessary, however, for mixtures

Stepwise chromatography

S/032/63/029/001/002/022

AUTHOR: Zhukhovitskiy, A. A.; Grigoryan, V. A.; Mikhalik, Ye.

TITLE: The surface effect of a chemical process

SOURCE: AN SSSR. Doklady*, v. 155, no. 2, 1964, 392-394

TOPIC TAGS: Thermoelectric phenomena, free energy conversion, thermodiffusion, electrodiffusion potential, temperature gradient, surface energy, phase contact area, surface tension, initial state, final state, nitrogen, capillary, gaseous mixture, interface, irreversible process, thermodynamics.

ABSTRACT: The subject under consideration in this article is the conversion of the free energy of a chemical process to surface energy. A chemical process may increase the phase contact area under certain conditions, i.e. it may affect the magnitude of surface tension. An increase of the interface under conditions of chemical equilibrium may result in an increasing number of moles of the surface-active intermediate compound which, generally speaking, is associated with the disappearance of the molecules in the initial and final states and ratios not in keeping with the equilibrium concentrations and the subsequent transition from one

Card 1/2

ACCESSION NR. AP4022722

state into another. The effect of the capillary activity of the chemical process can be illustrated by four groups of tests. A number of researchers noted that in the chemical process of the interphase transition of components in the metal-slag system, the metal drop found in the slag changes its form. They ascribed that phenomenon to the chemical interphase transition. Another qualitative illustration of the reduction of surface tension (σ) as a result of the simultaneous chemical process is the self-emulsification initiated by the chemical reaction. The surface tension was measured by two methods: the maximum pressure in a bubble and the drop count method. The results were compared and found to be similar. Orig. art. has: 2 figures and 5 formulas.

AUTHOR: Zhukhovitskiy, A. F. Engineer

TITLE: Some production and labor organization aspects in comprehensively automated industry

PERIODICAL: Vestnik mashinostroyeniya, no. 2, 1961, 63 - 76

TEXT: The author discusses the organization matters in view of the automation progress in the USSR and the old management ways that are hampering progress in already existing automated shops. It is pointed out that the production planning and accounting is simple in an automated shop, and the old production preparation ways are out of place. The functions are discussed of the shop dispatcher in charge of shift, transfer machine line foremen and setter, etc. down to shop store labor and cleaning teams, and a management plan is suggested. The idea is illustrated by management plans occupying ten pages and showing the organization as it is in nonautomated shops and as it is suggested for the switchover period to automation and for automated production. The technical progress function, or rationalization, would be left to the new functionaries - the line foremen and

TITLE: Automatic Compensation of Electro-Extensometric Balances

PERIODICAL: Izmeritel'naya tekhnika, 1959, Nr 10, pp 16-18 (USSR)

ABSTRACT: An automatic compensator without the slide-contact rheochord was constructed by the author for electro-extensometric balances. The wire changers, which form the resistance of the arms of a compensating bridge, are mounted on a small steel rod (Fig 1) of equal resistance to bending. The free end of the rod is displaced by a servo-mechanism. When the rod is bent, the resistance of the bridge arm varies. The author gives an analytical and graphic computation of the process. There are 2 diagrams and 2 graphs and 1 table.

TITLE: Magnesium Vapor Pressure in a MgO-Si System

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Tsvetnaya metallurgiya, 1960, Nr 1, pp 115-118 (USSR)

ABSTRACT: A reaction between magnesium oxide and silicon in vacuum at high temperature forms metallic magnesium and a solid slag which consists of $2MgO \cdot SiO_2$. Magnesium vapor pressure was determined by several authors but their results differed greatly. The author verified these data using the method of small orifice through which vapors escape and their pressure can be determined according to the equation:

$$P = k \frac{q}{fs} \sqrt{\frac{2\pi RT}{Mi}}, \qquad (2)$$

Card 1/6

where P is the pressure under which vapor escapes, dyn/cm^2; q is magnesium quantity escaped through orifice, g; t is duration of heating at test temperature, sec; s is orifice area, cm^2; R is gas constant, erg/degree; T is absolute test temperature; M is molecular weight of magnesium vapor; K is corrective coefficient determined from a known vapor pressure, in this case Ag. This method was described in detail in a previous work by the author (Trudy SKGMI, Vol 15, 1957). S. Tararin, V. Zagryadskiy, and A. Iosifova participated in the present work. The materials used in the tests consisted of strongly calcined magnesite (in %, 91.22 MgO, 0.65 CaO, 3.46 Fe_2O_3, 2.57 SiO_2, and 1.95 other matter) and technical grade silicon from Ural Aluminum Plant (Ural'skiy alyuminiyevyy zavod). The experimental device consisted of the furnace, retort, and reaction vessel as shown in Fig. 1 and 2. Magnesite and silicon were pulverized, screened, briquetted, and charged into the crucible. Vapor pressure was determined at 1,423 and

SOV/149-60-1-16/27

1,473° C. Magnesium condensate was collected after a certain recorded time, dissolved in acetic acid, and its quantity determined. Equation (2) was used, into which a corrective coefficient K = 1.48, as determined from previous tests (with Ag), was introduced. After substitution of test figures Eq. (2) can be written as:

$$P \text{ mm Hg} = 0.11 \, q \sqrt{T} \qquad (3)$$

According to this equation the vapor pressure was calculated and found: 0.27 mm Hg at 1423° K and 0.40 mm at 1473° K. These data are near to those of V. G. Zhivov (1.82 mm at 1,200° C) but differ widely from those of Pidgeon and King (34.2 mm at the same temperature). The latter are evidently incorrect. There are 2 figures; 1 table; and 3 references. 2 Soviet, 1 U.S. The U.S. reference is: Pidgeon, King, Phys. Chemistry Pross. Metall, 1948.

TITLE: On the convective instability of a two-component mixture in a gravitational field

PERIODICAL: Prikladnaya matematika i mekhanika, v. 27, no. 2, 1963, 301-308

TEXT: The authors investigate the problem stated, which so far has been largely ignored by theoretical and practical research workers. The problem of the stability of the convection of a two-dimensional vertical layer of the mixture heated from below is solved exactly on the basis of the convective equations of I. G. Shaposhnikov (PMM, v. 17, no. 5, 1953). The possibility of a state of equilibrium is demonstrated, and it is shown that, for equilibrium, the density gradient will be constant and vertical. In contra-distinction from the case of a pure medium, investigated by V. S. Sorokin (PMM, v. 17, no. 1, 1953) there are two possible types of disturbance of the equilibrium position which may arise -

Card 1/2

i.e. monotonic and oscillatory disturbances. Equations are deduced, in terms of the ordinary and diffusional Rayleigh numbers, for the 'neutral' line and the 'neutral' oscillation respectively, (i.e. the line or oscillation which separates those disturbances which are damped from those which increase monotonically in the second case). It has so far been assumed that the equilibrium gradients of temperature and concentration are independent. In conclusion, the authors investigate the stability of equilibrium when these gradients are connected by some law. It is shown that for normal thermodiffusion only unstable relatively monotonic disturbances are possible, while for anomalous thermodiffusion oscillatory instability is possible, and also monotonic instability with heating from above. There are 3 figures.

experimental arrangement is shown (Fig 1), the primary elements of which are a monocrystal spectrometer, a scintillation counter and a Geiger counter. After a closer description of the system, an interpretation is given of measuring results. The formula is first supplied, by which the μ/ϱ was determined at an accelerating voltage of 8 kv up to 25 kv with 2 ma. The background caused by the dispersion of the X-ray is stated as being $< 1\%$. Table 3 supplies the results obtained by the authors with the Geiger and scintillation counter, and the respective mean values are specified. Table 4 contains the values of μ/ϱ computed with the abovementioned formula for the various wavelengths, and their error is also given. A diagram represents the dependence of I/I_{sp} and μ/ϱ on the wavelength in beryllium. A description follows of results obtained from similar investigations on aluminum; they are summarized in two tables. The result obtained from the comparison between the Russian industrially-produced vacuum-tight beryllium plates and the beryllium window of an American X-ray tube for structural investigations of the Firm Machlett is

regarded as an essential result yielded by these investigations, revealing the μ/ϱ of the American tube to be larger by 2 to 2 1/2 times than that of the Russian type. Finally, the authors thank G. M. Nikolayenko, M. M. Umanskiy and Ye. M. Fridman for assistance and advice given.There are 2 figures, 6 tables, and 10 references, 5 of which are Soviet.

TITLE: Separation of selenium from tellurium based on different solubilities of magnesium salts of selenic and telluric acids

SOURCE: IVUZ. Khimiya i khimicheskaya tekhnologiya, v. 9, no. 6, 1966, 869-872

TOPIC TAGS: selenium, tellurium, magnesium compound, selenic acid, solubility

ABSTRACT: A technique is proposed for separating selenium from tellurium, based on the different solubilities of magnesium selenate and orthotellurate, both of which are formed by roasting selenium and tellurium in air with magnesium oxide or Eschka's reagent. The solubility of the orthotellurate Mg_3TeO_6 was determined at several temperatures. It is shown that if Se and Te are roasted with a 20 to 30-fold excess of Eschka's reagent for 40 min at 800°C, a water-soluble selenate is formed together with an almost insoluble magnesium orthotellurate. The sinter is leached out with water and filtered. The filtrate contains the selenium, and the insoluble residue contains the tellurium. The following elements do not interfere with the separation: iron, copper, lead, silver, zinc, antimony, bismuth, chromium, aluminum, silicon, barium, calcium, sulfur, i. e., all the elements usually found in various

TITLE: Use of nonaqueous solvents for separating radioisotopes by precipitation and leaching

SOURCE: AN SSSR. Sibirskoye otdeleniye. Izvestiya. Seriya khimicheskikh nauk, no. 3, 1965, 28-32

TOPIC TAGS: adsorption, beryllium, lithium, sodium, magnesium, radioisotope, chemical precipitation

ABSTRACT: A method was developed for separating the radioisotopes sodium-22 and beryllium-7 without a carrier by precipitating the target element (magnesium in the case

Card 1/2 UDC: 541.15+542.6.621.039.554

L 36240-66

ACC NR: AP6005419

of Na^{22} and lithium in the case of Be^{7}) in a mixed aqueous-organic solvent. The conditions of maximum precipitation of the target element with a minimum occlusion of the radioisotope were determined. The adsorption of the microcomponent (radioisotope) by the precipitate of the macrocomponent was studied in aqueous-organic media (water-acetone, water-ethanol, water-dioxane). The best medium for a maximum extraction of sodium were found to be 10—15% mixtures of acetone or dioxane with water. In the beryllium-lithium system, only ethanol was employed as the organic solvent. An experimental study of the adsorption of beryllium by the lithium sulfate precipitate showed that up to a Be concentration of ~5 x 10^{-5} g-ion/ml, the adsorption isotherm is linear and obeys Henry's law. However, the character of the occlusion of the microcomponent by the precipitate cannot be judged on the basis of this isotherm; and no definite results were obtained for the adsorption mechanism. TITLE: Use of nonaqueous solvents for isolation of radioactive Na sup 22 from irradiated magnesium

SOURCE: Radiokhimiya, v. 8, no. 1, 1966, 63-66

TOPIC TAGS: sodium, magnesium, stoichiometric mixture, radiation chemistry, chemical separation, chemical precipitation, organic solvent, solubility, desorption

ABSTRACT: A method is proposed for recovering Na^{22} without using a carrier. Irradiated magnesium was dissolved in almost a stoichiometric amount of sulfuric acid. The solution was evaporated until a film began to form and an equal or somewhat larger volume of ethanol was added. The solution was carefully stirred and the liquid with the crystalline precipitate of magnesium sulfate was decanted onto a glass filter. For more complete isolation of Na^{22}, the precipitate was washed five to six times with small portions of ethanol. The extent of Na^{22} recovery was 95-97%. Separation of sodium from small amounts of magnesium passing into the water-ethanol solution was achieved by ion-exchange on the KU-2 cation exchange resin directly from the water-alcohol

filtrate. An 0.1 N HCl solution was used in eluting the Na^{22}. In the present report, the authors examine the possibility of using organic solvents other than ethanol, e.g. acetone and dioxane. It was shown that the nature of the organic solvent added to precipitate magnesium sulfate does not affect the composition of the crystal hydrate formed. The solubility of magnesium sulfate in ethanol, acetone, and dioxane, and in their mixtures with water at 20°C was determined. The desorption of Na^{22} from the surface of crystalline magnesium sulfate by these solvents was studied. It was established that solutions of acetone and dioxane containing 10 - 20% water exceed ethanol in desorptive capacity and are preferred for recovering radioactive Na^{22} from a magnesium target. TITLE: Some problems of the geoeffect of solar corpuscular streams 12

SOURCE: Geomagnetizm i aeronomiya, v. 6, no. 2, 1966, 197-204

TOPIC TAGS: solar corpuscular radiation, magnetohydrodynamics, geomagnetic disturbance, geomagnetic field, shock wave, solar plasma

ABSTRACT: The magnetic field of solar corpuscular streams plays the role of an intermediary in the interaction of streams with the earth's magnetosphere, leading to an increase of the effective cross section of interaction determining the possibility of the injection of solar plasma into the earth's magnetosphere, changing the degree of the frictional effect during the interaction, etc. Among the problems discussed in this paper are the conservation of the magnetic flux, the impossibility of penetration of the field of the flux into the earth's magnetosphere and the associated need for a magnetohydrodynamic interpretation of the theory of geomagnetic disturbances. No solution is found to the most important problem -- the mechanism of magnetospheric energy transfer, but it is believed that several mechanisms are in-

Card 1/2

L 39894-66

ACC NR: AP6018096

volved at the same time: 1) as a result of turbulence at the boundary small blobs of plasma can enter the magnetosphere and be trapped by the geomagnetic field; the field in the blobs, taking their smallness into account, should rapidly attenuate; 2) magnetohydrodynamic waves forming at the boundary of the magnetosphere can become shock waves upon penetration into the magnetosphere with corresponding energy dissipation and heating of the plasma of the magnetosphere; 3) in the transition region between the magnetopause and the standing shock wave there is a turbulent region which can be considered an isotropic group of sonic waves. Taking into account the relative motion of plasma in this region and in the outer part of the magnetosphere it is possible to explain transfer within the magnetosphere to 10^{19} ergs/sec as a result of wave refraction at the boundary of the magnetosphere, apparently adequate to explain storm energy; 4) the mechanism of nonlinear interaction of electrons and possible ionic sonic waves in the unstable transition region of interaction of the solar wind with the earth's magnetosphere. Orig. art. has: 1 figure, 1 table and 10 formulas. [JPRS]

TEXT: A calculation and description are presented of an arrangement devised as a standard for testing and graduating instruments for measuring strengths of weak magnetic fields. The arrangement consists of a Helmholtz coil system with a provision for compensation of the earth magnetic field and its variations. For compensation of the variations a system was employed with a strong negative feedback and variometers to indicate the vertical and horizontal components of the earth's field. The current in the coils was measured by a compensation method. The estimated error is 0.02 and

TITLE: A solder for soldering. Class 49, No. 170268

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 8, 1965, 86

TOPIC TAGS: solder, soldering, silver, tin, copper, antimony, lead, phosphorus

ABSTRACT: This Author Certificate presents a solder for soldering electric conductors with silver-silicate strips, containing tin, lead, antimony, and copper. To diminish the dissolution of silver in the silver-silicate strips and to strengthen the connection, 5% of silver and 0.1% of phosphorus are introduced into the solder, while its other components are held at the following percent composition:

tin	40.0
copper	5.0
antimony	1.5
lead	remainder.

AUTHOR: Zhukovskaya, N. A., and Ol', A. I.

TITLE: Change in the amplitude of the diurnal variation of the cosmic-ray intensity in relation to the magnetic activity

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 12, 1961, 10, abstract 12G57 (V sb. Variatsii kosmich. luchey i solnechn. korpuskulyarn. potoki. no. 2. M., AN SSSR, 1960, 101-104)

TEXT: The dependence of the amplitude of the diurnal variation of cosmic rays on the magnitude of K--the index of geomagnetic activity during the solar activity maximum (1957)--is established. The data were divided into 5 groups depending on the magnitude of the diurnal sum of the K-indices--ΣKp. It is shown that the amplitude of the diurnal variation increases

Card 1/2

Change in the amplitude...

S/169/61/000/012/078/089
D228/D305

with the growth of ΣKp to 19 - 23, and that it then sharply decreases at values of $\Sigma Kp = 24 \div 33$. A further increase in in the amplitude is observed at $\Sigma Kp = 34$. An analogous relationship is also detected for the period of the solar activity minimum (1954). Subsequent analysis disclosed that the mean-daily intensity values for days with $\Sigma Kp = 24 \div 33$ show no anomalous behavior. The possible causes of the detected effect are discussed. TITLE: On the existence of a stellar-diurnal variation of meson intensity in cosmic rays

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 5, 1961, 13, abstract 5 G 105. (Tr. Yakutskogo fil. AN SSSR, Ser. fiz., 1960, no. 3, 140-144)

TEXT: On the basis of data on intensity variations of the hard cosmic ray component that were obtained in Moscow, Yakutsk, Tikhaya Bay, Tokio and Freiburg, the authors investigated the presence of stellar-diurnal variation. In 1953 and 1955 the average monthly vectors of solar-diurnal variation corrected for the temperature effect evinced well expressed phase constancy. In 1954 the direction of the vector of solar-diurnal variation was shifted counterclockwise; at Tikhaya bay the phase change amounted to 180°. In contrast to this, it turned out that the phase of stellar-diurnal variation in 1954 was distinguished by high

Card 1/2

VB

constancy. These facts indicate that during a minimum of solar activity stellar-diurnal variation, the amplitude of which becomes comparable with that of solar-diurnal variation, has predominant importance. The authors emphasize the necessity of further study of the existence of stellar-diurnal variation by means of more extensive observation data.

ABSTRACT: The properties and structure of lithia-aluminosilica glasses catalyzed by TiO_2 and treated within a wide range of temperatures have been investigated. Special attention was paid to glasses the composition of which was close to spodumene (SiO_2 - 60.5; Al_2O_3 - 28.0; Li_2O - 6.5; TiO_2 - 5.0 weight %). The results cover the dependence of the index of refraction and glass density on the duration of treatment, the comparative x-ray and infrared reflection spectra for glasses treated at different temperatures, and the dependence of the index of refraction and glass density on treatment temperature. Curves of the differential thermal analysis are also given. The results show that at temperatures of 700 to 800C the resulting crystals

belong basically to the eucryptite-like solid solution. By their chemical composition these crystals are close to spodumene. At 890C, the basic crystalline phase becomes apparently identical to the β modification of spodumene, and the solid solution is now of the spodumene type. Orig. art. has: 6 figures.
